Cache Mirroring on Cloud servers.

Hi,

Can a Cache Mirror be used in the cloud ? (ie stand up a Primary and Backup member instances in a High Availability Cache Mirroring configuration)

I'm investigating the validity of this configuration, because I was of the understanding that this may not possible due to these cloud servers not (typically) having fixed ip addresses, which interferes with the Virtual IP settings for the mirror set.

Is this correct, and if there are workarounds (like Load Balancing ?) can I have details on how this should be configured ?

I'm assuming other options like traditional Windows Clustering, or a VMWare High Availability architecture remain valid options, but I'm interested on any approaches or experiences used to date hat have worked.

Thanks,

Steve.
