OpenAM interface question...

I'm VERY novice on all things "OpenAM", and beyond knowing that Caché supports working with OpenAM, I have nothing else to go on.

The documentation doesn't seem to be very deep on the nature of how this works beyond a single paragraph saying it's supported for Single Sign On (SSO).

For Caché to use this, I get that there is an environment variable (REMOTE_USER) which is set to "something", but it's not clear to me how this ends up mapping to a provisioned caché user (or LDAP provisioned user for that matter) and ultimately to the %Roles in effect and subsequent system access.

Can someone please enlighten me with a few more details of how this works?

Thanks
