Using Docker for standalone deployment of Ensemble

How suitable is Docker for standalone deployment of an Ensemble version and Ensemble application together?

The context is deployment by an application partner of an integration application and the supporting Ensemble version as a single package (single file ideally), to multiple environments and to multiple customer sites.

I don't have experience with Ensemble on Docker so I'm wondering what gaps and pitfalls may exist.

The focus of the question is deploying the Ensemble product and application code - I do understand that consideration is needed on management of the application data, including any retained Ensemble messages.

This would be for new applications on Ensemble 2016.1+ on Linux. Linux containers on Windows are of interest - but how mature is the Windows support for them?
