Scripted/Automated Production Deployment?

I am looking for a way to deploy production changes (code and/or production configs) via script or some other systematic way other than the Ensemble/Deploy page in the Management Portal. My goal is to store these configurations in Subversion, then have a piece that can pull the XML from source control and deploy it to a given server. Is there some kind of script that I can run on a given server to perform this deployment? If so, I can tie it up with Subversion using another tool that I have access to.

If it helps, we are running Cache 2016.1 (HealthShare 15.01) on Red Hat Enterprise Linux 7.

Thanks!

Greg
