## How to set \$\$\$envCallerErrorInfoGet on windows to get the location information within a exception.

Class documentation:

class %Exception.General extends [AbstractException](#)

Simple exception class that can be throw in user code. You can throw this with code similar to:

```
Throw ##class(%Exception.General).%New(name,numericCode,location,data)
```

The name is a string name for the exception, the numericCode is a numeric error code. If the location field is blank and \$\$\$envCallerErrorInfo is defined then the system will attempt to fill in this location where the exception was thrown from automatically. You can pass additional exception data in the data argument.

Does any boding knows how to set the \$\$\$envCallerErrorInfo variable? Ensemble is running on Windows PC.
