## SQL Inbound Adapter - Last Row ?

Hi,

The Ensemble SQL Inbound Adapter executes a user defined query, and calls the OnProcessInput method of the Business Service with information about an individual row of the executed query.

If the query provided by the user (and executed by the adapter), returned multiple rows, then, OnProcessInput is called multiple times, once for each row.

Within the OnProcessInput method, however, is there a way to know that the row that is currently being processed is actually the last row of the query.

Thanks

Steve
