Dynamically Creating Class (Reflection in C#)

I need to dynamically create a class based on a parameter passed into a class method. Basically the method takes in a string that contains the name of the class I need to create a new instance of.

I need something along these lines.

```
ClassMethod someMethod(className As %String)
{
 set classObject = ##class(className).%New()

...
}
```

Trying to do this right results in a class not found error because it seems to be treating the variable as a literal string.

#Object Data Model #Caché
