storage of usernames, passwords in plain Cache systems 2017.2 version

I need to automate the handling of usernames passwords, serverNames etc for use in the sending and receiving of emails, logging into SFTP servers etc etc for use within COS code
To manage external passwords we could use LastPass or any other proprietary password loggers, but I need to be able to call them as part of the automation (COS code) and occasionally visually look them up to "remind" the staff of their passwords.

any suggestions as to the best class data constructs to handle this scenario. Should the whole table be encrypted, only the passwords etc.

each employee has their own login details, past password storage (non-re-use) could be useful.

we're talking of 200-300+ passwords here.
