Creating multiple HL7 messages based on data contained in one inbound HL7 message

I'm looking for options to create multiple DFT HL7 messages based on data contained in a ZCO segment in a single inbound DFT message. I have the following ZCO segment:

```
ZCO|CCC^Charge Code|1306794,1071301,23510,1071424|MFCD^Charge Code|14232,3542||||
```

In this example, I need to create a new DFT message based on the data contained in ZCO:2. Each code needs to be in its own DFT message and put in FT1:7.1. The number of codes will vary for each inbound message, but each code will need to create its own outbound message to the client.
