## Transaction suspencion

It 's often useful to make changes inside the current transaction, that would not be rolled-back if transaction is rolled-back. For example to do some logging.

This can be achieved by using global that is mapped to temporary database -- IRISTEMP. All globals that start with ^IRIS.Temp\* are mapped to IRISTEMP by default. Problem with such approach is that IRISTEMP is cleaned on InterSystems IRIS restart, so this log is lost.

What else you can do is -- suspend transaction temporarily, do the logging, and then resume the same transaction.

Method that suspends/resumes transaction is <u>\$System.Process.TransactionsSuspended(switch)</u>.

If switch is 1 transactions are suspended, if switch is 0 transactions are resumed.

For example:

```
USER>tstart
TL1:USER>set ^a=1
TL1:USER>do $system.Process.TransactionsSuspended(1)
TL1:USER>set ^log($I(^log)) = "we set ^a to 1"
TL1:USER>do $system.Process.TransactionsSuspended(0)
TL1:USER>trollback
USER>zw ^a
USER>zw ^a
USER>zw ^log
^log=1
^log(1)="we set ^a to 1"
```

Notice, in this case changes in Alog global are still journaled (if it is mapped to journaled-database).

Some details are in <u>Suspending All Current Transactions</u> " section of<u>Transaction Processing</u> " chapter of documentation.
