Adding a new field to a web service API call

Currently one of our applications, coded in Cache, performs web service API calls out to one of our vendors. We now need to be able to send a Client ID in the portion of the Soap envelope.

I think I have a clue of what I need to do but not 100% sure. We were thinking we could use the method %SOAP.WebClient.SetHTTPHeader(field name, value) but when I have tired using this method and looked at the Soap log to see what is sent, the field is never showing. I realized I could be setting the wrong object using the method.

I have been looking at the documentation but I have not found what I need yet.

This is not using REST.

I would appreciate any suggestions.

Thanks.

Kris
