String manipulation on a field during transformation using a ClassMethod.

I need to do some nifty string manipulation on a source property. I will not be able to do it with the functions available (with the knowledge that I have of what is available). Could I call a ClassMethod to do this for me? This is what I want to do: The source property is "[myemail@myemaildomain.co.uk](#)". I need to add the text "test" to the beginning of that string. "[testmyemail@myemaildomain.co.uk](#)". That should be simple enough, but then I have to do this as well, "[testmyemail@myemaildomaintest.co.uk](#)". Note the additional "test" added after "myemaildomain".
