Is it possible to acquire the Jobnr/Owner from a remotlock with ^$LOCK?

Hi,

in our system we usually display an information if someone locks data that another user tries to edit. Like: "Data locked by <user>/<program>"

We have a global that is set at userlogin with following information:

^BAO20(0,3,$job) = "<user>;<program>"

We show that information by getting the jobnr/owner from the locktable ^$LOCK("<ref>","OWNER") and looking at ^BAO20.

We recently added applicationservers to our system and the result is quite interesting. Instead of getting the jobnr from ^$LOCK when it's a remotelock I only get the name of the applicationserver e.g. APPAIXVK3. It's a documented behaviour.

The result is that we can't get the user information of ^BAO20 due to the jobnr.

Is there a way to get the jobnr from an remotelock by calling ^¦¦"APPAIXVK3"¦¦$LOCK or is there no way?

Regards

Jochen
